コース: [ALX Software Engineering](#)

# Bash Notebook

作家: [Anrich Tait](#)

## **Abstract**

My notes on the bash shell, this will also include some useful information regarding Unix systems. Most of my learning in this regard was in relation to my software engineering studies.

# Chapter 1

## Shell Basics

### 1.1 Objectives

1. What is the shell?
2. Navigation.
3. Looking around
4. A guided tour
5. Manipulating files
6. Working with commands
7. Reading man pages
8. Keyboard shortcuts
9. LTS
10. Shebang

### 1.2 Resources

1. [What is the shell?](#)
2. [Navigation](#)

3. [Looking around](#)
4. [A guided tour](#)
5. [Manipulating files](#)
6. [Working with commands](#)
7. [Reading man pages](#)
8. [Keyboard shortcuts](#)
9. [LTS](#)
10. [Shebang](#)

## **Man Pages**

cd, ls, pwd, less, file, ln, cp, mv, rm, mkdir, type, which, help, man

## 1.3 Notes

### 1.3.1 What is the shell?

The shell is a command line interface (CLI) that takes commands and passes them to this operating system.

Bash is the most common example of a shell program, others include: ksh, tcsh and zsh.

Most interactions with the shell are done through a terminal like gnome, alacritty or kitty.

**NOTE:** Make sure that the last symbol of your shell prompt is not `#`. If it is this means that you are in sudo (super user) mode and this can be dangerous.

### 1.3.2 Navigation

Nothing much here for me to learn, maybe important to note though:

Important facts about file names:

1. File names that begin with a period character are hidden. This only means that `ls` will not list them unless we say `ls -a`. When your account was created, several hidden files were placed in your home directory to configure things for your account. Later on we will take a closer look at some of these files to see how you can customize our environment. In addition, some applications will place their configuration and settings files in your home directory as hidden files.
2. File names in Linux, like Unix, are case sensitive. The file names "File1" and "file1" refer to different files.
3. Linux has no concept of a "file extension" like Windows systems. You may name files any way you like. However, while Linux itself does not care about file extensions, many application programs do.
4. Though Linux supports long file names which may contain embedded spaces and punctuation characters, limit the punctuation characters to period, dash, and underscore. Most importantly, do not embed spaces in file names. If

you want to represent spaces between words in a file name, use underscore characters. You will thank yourself later.

### 1.3.3 Looking around

A closer look at the long format: `ls -l`

|            |   |    |    |        |        |       |               |
|------------|---|----|----|--------|--------|-------|---------------|
| -rw-----   | 1 | me | me | 576    | Apr 17 | 2019  | weather.txt   |
| drwxr-xr-x | 6 | me | me | 1024   | Oct 9  | 2019  | web_page      |
| -rw-rw-r-- | 1 | me | me | 276480 | Feb 11 | 20:41 | web_site.tar  |
| -rw-----   | 1 | me | me | 5743   | Dec 16 | 2018  | xmas_file.txt |

|       |       |       |       |       |       |       |                   |
|-------|-------|-------|-------|-------|-------|-------|-------------------|
| ----- | ----- | ----- | ----- | ----- | ----- | ----- | -----             |
|       |       |       |       |       |       |       |                   |
|       |       |       |       |       |       |       | File Name         |
|       |       |       |       |       | +     | ---   | Modification Time |
|       |       |       |       | +     | ----- |       | Size (in bytes)   |
|       |       |       | +     | ----- |       |       | Group             |
|       |       | +     | ----- |       |       |       | Owner             |
| +     | ----- |       |       |       |       |       | File Permissions  |

- File name: Name of file or directory
- Modification time: Last time the file was modified
- Size: size of the file in bytes
- Group: Group that has file permissions other than the file owner
- Owner: The user that owns the file.
- File Permissions: A representation of the file's access permissions. The first character is the file type, "-" indicates a regular or ordinary file. A "d" indicates a directory. The second character represents the read, write and execution rights of the file owner. The third represents the rights of the file's group. The last represents the permissions granted to everyone else.

| Directory      | Description   |
|----------------|---|
| /              | The root directory where the file system begins.  |
| /boot          | Linux kernel and bootloader directory. The kernel is a file called vmlinuz.   |
| /etc           | Configuration files, important locations include: /etc/passwd - user info, /etc/fstab - mounted devices(disk drives), /etc/hosts - Network host names and IP addresses, /etc/crontab - system service scripts run at boot time. |
| /bin, /usr/bin | Most of the system programs.  |
| /usr           | folders/files that support user applications  |
| /usr/local     | Used for installation of software (user). Most commonly in /usr/local/bin   |
| /var           | Files that change as the system runs, including logs and spools.  |
| /lib           | The shared libraries  |
| home           | user files  |

The list goes on and on, do research to find specific files.

### 1.3.4 Manipulating Files

**Commands to know/understand:**

1. cp: copy files and directories
2. mv: move or rename files and directories
3. rm: remove files and directories
4. mkdir: make directories

**Wildcards:** Wildcards allow the user to specify groups of filenames. This makes mass file manipulation much easier.

| Wildcard    | Meaning  |
|-------------|--|
| *           | Matches any characters   |
| ?           | Matches any single character                                     |
| characters  | Matches any character that is part of the set characters.        |
| !characters | Matches any character that is not a member of the set characters |

Here are some examples of patterns and what they match.

| Pattern | Matches   |
|---------|---|
| *       | All filenames   |
| g*      | All filenames that begin with the character "g"                                       |
| b*.txt  | All filenames that begin with "b" and end with ".txt"                                 |
| Data??? | Any filename that begins with the characters "data" followed by any other characters. |

## 1.4 Working with commands

### Commands to know/understand

1. type: Display information about command type
2. which: Locate a command
3. help: Display reference page for shell builtin
4. man: Display an on-line command reference

### What are "Commands"

Commands fall into 4 categories:

1. Executable programs: programs that can be executed
2. A command built into the shell: or "shell builtins. Like, "cd"
3. A shell function: Miniature shell scripts.
4. An alias: Commands that the user defines, built from other commands.

# Chapter 2

## Shell permissions

### 2.1 Resources

1. [Permissions](#)

**man or help pages:**

1. chmod - modify file access rights
2. sudo - enter super user mode or execute a command as such
3. su - temporarily enter sudo mode
4. chown - change file ownership
5. chgrp - change a file's group ownership
6. id - print effective user and group IDs
7. groups - display current group names
8. whoami - print effective username
9. adduser - ?
10. useradd - create a new user or update default new user info
11. addgroup - ?

## 2.2 Permissions Notes

Each file/directory is assigned access rights for the owner of the file, members of a group of related users and everybody outside of the afore-mentioned groups.

Rights can be assigned to read, write and execute a file.

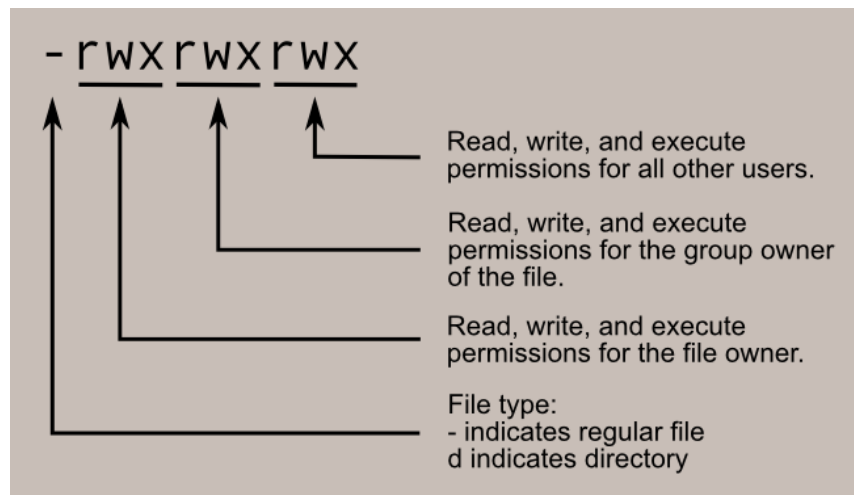

As an example the ls command will be used to look at the 'bash' program located in the /bin directory:

```
~ x ls -l /bin/bash
-rwxr-xr-x 1 root root 1071664 Feb  2 08:38 /bin/bash
```

Here we can see:

1. The file "/bin/bash" is owned by user 'root'
2. The superuser has the right to read, write and execute
3. The file is owned by the group "root"
4. Members of the group 'root' can also read and execute
5. Everybody else can read and execute the file

Below is graphic showing what each portion of the first listing represents:

## 2.3 Look at all the pretty commands

### 2.3.1 chmod

Used to change the permissions of a file or directory. To use it specify the desired permission settings and the file or files that are to be modified.

There are two ways to do this, the following method uses the octal notation method.

Think of the permission settings as a series of bits (like a computer):

```
rwX  rwX  rwX  =  111  111  111
rw-  rw-  rw-  =  110  110  110
rwX  ---  ---  =  111  000  000
```

and so on...

```
rwX  =  111  in binary =  7
rw-  =  110  in binary =  6
r-x  =  101  in binary =  5
r--  =  100  in binary =  4
```

No we can represent each of the three sets of permissions, (owner, group and other) as a single digit to create a convenient way of expressions the permission settings.

For example to set the permissions of a file to have read and write permission for the owner, but wanted to keep the file private from others we would use:

```
~ > chmod 600 some_file|
```

### **File Permissions:**

Below is a table of common settings for files, the ones starting with '7' are used with programs since they enable execution. The rest are other kinds of files:

1. 777 - (rwxrwxrwx) No restrictions on permissions, All groups can do everything. (BE WARNED)
2. 755 - (rwxr-xr-x) File owner can read, write and exec, All others may read and exec.
3. 700 - (rwx——) File owner can read, write and exec. Nobody else can do anything.
4. 666 - (rw-rw-rw-) All users may read and write the file.
5. 644 - (rw-r-r-) File owner may read and write, others can only read.
6. 600 - (rw——-) Owner can read and write a file. All other have no rights.

### **Directory Permissions:**

The chmod command can also be used to change directory permissions.

In this case octal notation is also used but the r, w and x meanings are different:

1. r - Allows the contents of the directory to be listed if the x attribute is also set
2. w - Allows files within the directory to be created, deleted or renamed if the x attribute is also set
3. x - Allows a directory to be entered (cd dir)

Here are some common settings for directories:

1. 777 - (rwxrwxrwx) No restrictions on permissions. Anybody may list files, create new files in the directory and delete files in the directory. Generally not a good setting.
2. 755 - (rwxr-xr-x) The directory owner has full access. All others may list the directory, but cannot create files nor delete them.
3. 700 - (rwx——) The directory owner has full access. Nobody else has any rights. This setting is useful for directories that only the owner may use and must keep private.

### 2.3.2 chown

Change file ownership.

Example:

Change the owner of some\_file from "me" to "you":

```
~ > sudo chown you some_file|
```

### 2.3.3 chgrp

Change the group ownership of a file or directory.

Example:

```
~ > chgrp new_group some_file|
```

# Chapter 3

## Shell, I/O Redirections and filters

### 3.1 Learning objectives

1. Understanding Shell, I/O Redirection
2. What are special characters and what to do with white spaces, single quotes, double quotes, backslash, comment, pipe, command separator, tilde.
3. How to concatenate files and print on the standard output
4. How to reverse a string
5. How to remove sections from each line of files
6. what is the `/etc/passwd` file and its format
7. what is the `/etc/shadow` file and what is its format

### 3.2 Resources and man pages

Links:

1. [Shell I/O Redirection](#)
2. [Special characters](#)

**man pages**

1. `echo`

2. cat
3. head
4. tail
5. find
6. wc
7. sort
8. uniq
9. grep
10. tr
11. rev
12. out
13. passwd (man 5 passwd)

## 3.3 I/O Redirection

I/O redirection is another way of saying input and output redirection, specifically how a user can redirect a command's output to a file, device and other commands.

### 3.3.1 Standard Output Redirection

Most command line program send their results to the standard output, by default the standard output directs it's contents to the display.

One way the user can redirect this standard output is by using the '>' characters.

```
$ ls > file file_list.txt
```

In the above example the `ls` command is executed and the results are outputted to a file named `file_list.txt`. Since the `ls` output was redirected to a file, no output will be displayed in the terminal.

In the above example every time the command is run `file_list.txt` will be overwritten, we can append the output (add to end of file) by using two `'>'` characters.

```
$ ls >> file_list.txt
```

### 3.3.2 Standard Input Redirection

Many commands accept input from something called standard input. Standard input can receive input from the Keyboard (via user in terminal) or from files (such as `file_list.txt`) through redirection.

We can redirect standard input from a file by using the `'<'` character:

```
$ sort < file_list.txt
```

In this example the **`sort`** command is used to process the contents of the file. The 'sort' command's description is as follows: Write sorted concatenation of all FILE(s) to standard output.

The output of this command will be sent to the standard output and displayed on the terminal screen for the user to see. If you wish to send the sorted list to another file it can be done like this:

```
$ sort < file_list.txt > sorted_file_list.txt
```

### 3.3.3 Pipelines

Pipelines make it possible to feed the output of one command into the input of another. Indeed creating some powerful capabilities. Example:

```
$ ls -lt | less
```

This example shows how the `ls` command can be fed into the 'less' command. Essentially creating a scrolling output.

**Some other examples to try**

1. `ls -lt | head`: Displays the 10 newest files in the current directory.

2. `du | sort -nr` : Displays a list of directories and how much space they consume , sorted from the largest to smallest.
3. `find . -type f -print | wc -l` : Displays the total number of files in the current working directory and all of it's subdirectories.

### 3.3.4 Filters

Filters are frequently used with pipes to take input from one command and then output the result in standard output. This has a wide range of capabilities that allow the user to process or search for specific information.

Some common filters include:

1. `sort` : sorts standard input
2. `uniq` : removes duplicate lines of data
3. `grep` : outputs ever line that contains a specified pattern of characters
4. `fmt` : outputs formatted text
5. `pr` : splits data into pages with page breaks, headers and footers (in preparation for printing)
6. `head` : outputs first few lines of input
7. `tail` : outputs last few lines of input
8. `tr` : Translates characters (upper/lower case conversion, change line termination characters)
9. `sed` : Stream editor, more advanced text translations than 'tr'
10. `awk` : An entire programming language designed for constructing filters.

**Note:** Chapter 6 of The Linux Command Line covers this in more detail. I have the book in the extra resources directory.

Also consider reading more on [AWK](#)

## 3.4 Special Characters

In bash there is a concept of special characters, these are characters that carry out special instructions or have an alternate meaning. They are also known as *meta characters*

Some common examples of special characters:

| Char.    | Description  |
|----------|--|
|          | <i>Whitespace</i> — this is a tab, newline, vertical tab, form feed, carriage return, or space. Bash uses whitespace to determine where words begin and end. The first word is the command name and additional words become arguments to that command.   |
| \$       | <i>Expansion</i> — introduces various types of expansion: parameter expansion (e.g. <code>\${var}</code> or <code>\${var%}</code> ), command substitution (e.g. <code>\$(command)</code> ), or arithmetic expansion (e.g. <code>\$(expression)</code> ). More on expansions later.                               |
| ''       | <i>Single quotes</i> — protect the text inside them so that it has a <i>literal</i> meaning. With them, generally any kind of interpretation by Bash is ignored: special characters are passed over and multiple words are prevented from being split.   |
| ""       | <i>Double quotes</i> — protect the text inside them from being split into multiple words or arguments, yet allow substitutions to occur; the meaning of most other special characters is usually prevented.  |
| \        | <i>Escape</i> — (backslash) prevents the next character from being interpreted as a special character. This works outside of quoting, inside double quotes, and generally ignored in single quotes.  |
| #        | <i>Comment</i> — the # character begins a commentary that extends to the end of the line. Comments are notes of explanation and are not processed by the shell.  |
| =        | <i>Assignment</i> — assign a value to a variable (e.g. <code>logdir=/var/log/myprog</code> ). Whitespace is <i>not</i> allowed on either side of the = character.  |
| [ ]      | <i>Test</i> — an evaluation of a conditional expression to determine whether it is "true" or "false". Tests are used in Bash to compare strings, check the existence of a file, etc. More of this will be covered later.   |
| !        | <i>Negate</i> — used to negate or reverse a test or exit status. For example: <code>! grep text file; exit \$?.</code>   |
| >, >>, < | <i>Redirection</i> — redirect a command's <i>output</i> or <i>input</i> to a file. Redirections will be covered later.   |
|          | <i>Pipe</i> — send the output from one command to the input of another command. This is a method of chaining commands together. Example: <code>echo "Hello beautiful."   grep -o beautiful.</code>   |
| ;        | <i>Command separator</i> — used to separate multiple commands that are on the same line.   |
| { }      | <i>Inline group</i> — commands inside the curly braces are treated as if they were one command. It is convenient to use these when Bash syntax requires only one command and a function doesn't feel warranted.  |
| ( )      | <i>Subshell group</i> — similar to the above but where commands within are executed in a <i>subshell</i> (a new process). Used much like a sandbox, if a command causes side effects (like changing variables), it will have no effect on the current shell.   |
| (( ))    | <i>Arithmetic expression</i> — with an <i>arithmetic expression</i> , characters such as +, -, *, and / are mathematical operators used for calculations. They can be used for variable assignments like <code>(( a = 1 + 4 ))</code> as well as tests like <code>if (( a &lt; b ))</code> . More on this later. |
| \$( ( )) | <i>Arithmetic expansion</i> — Comparable to the above, but the expression is replaced with the result of its arithmetic evaluation. Example: <code>echo "The average is \$(( (a+b)/2 ))".</code>   |
| * , ?    | <i>Globs</i> — "wildcard" characters which match parts of filenames (e.g. <code>ls *.txt</code> ).   |
| ~        | <i>Home directory</i> — the tilde is a representation of a home directory. When alone or followed by a /, it means the current user's home directory; otherwise, a username must be specified (e.g. <code>ls ~/Documents; cp -johnd/.bashrc .</code> ).  |
| &        | <i>Background</i> — when used at the end of a command, run the command in the background (do not wait for it to complete).   |

```
$ echo "I_am_$LOGNAME"
I am lhunath
$ echo 'I_am_$LOGNAME'
I am $LOGNAME
$ # boo
$ echo An open\ \ \ space
An open  space
$ echo "My_computer_is_$(hostname)"
My computer is Lyndir
$ echo boo > file
$ echo $(( 5 + 5 ))
10
$ (( 5 > 0 )) && echo "Five_is_greater_than_zero."
Five is greater than zero.
```

# Chapter 4

## Shell, init files, variables and expansion

### 4.1 Learning objectives

1. What are the `"/etc/profile"`, `"/etc/profile.d"` and `".bashrc"` files?
2. What are local and global variables?
3. What are shell variables and how to use them?
4. What are shell expansions?
5. Shell arithmetic
6. Shell aliases

### 4.2 Resources and man pages

#### 4.2.1 Links

1. [Expansions](#)
2. [Shell arithmetic](#)
3. [Variables](#)
4. [Shell initialization files](#)

- 5. [Shell aliases](#)
- 6. [Technical writing](#)

## 4.2.2 man and help pages

1. `printenv` : Print the values of the specified environment VARIABLE(s). If no VARIABLE is specified, print name and value pairs for them all.
2. `set` : If no options or arguments are specified, set shall write the names and values of all shell variables in the collation sequence of the current locale.
3. `unset` : Each variable or function specified by name shall be unset
4. `export` : give export attribute to specified variables which will cause to be in the environment of subsequently executed commands
5. `alias` : Create alternate names for commands or string of commands to make your life easier
6. `unalias` : remove an alias
7. `.` : ?
8. `source` : Evaluate a file or resource as a Tcl script. Used after changes are made to `.bashrc` for them to take affect
9. `printf` : format and print data

## 4.3 The notes:

### 4.3.1 Expansions

Any command that is entered into the command line goes through several processes before the result is output. Consider how much impact the "\*" character can affect a command. This process is called expansion.

#### **Pathname expansion:**

The mechanism that makes wildcards work is called "pathname expansion". Consider how we can take the output of a normal 'ls' command and add a wildcard to it to display a different output.

```
[me@linuxbox me]$ ls
Desktop
ls-output.txt
Documents Music
Pictures
Public
Templates
Videos
```

Examples of expansions in this context:

```
[me@linuxbox me]$ echo D*
Desktop Documents
```

```
[me@linuxbox me]$ echo *s
Documents Pictures Templates Videos
```

```
[me@linuxbox me]$ echo [[:upper:]]*
Desktop Documents Music Pictures Public Templates Videos
```

### Tilde expansion

The " " (tilde) character has special meaning in bash. It is used to specify the home directory. Without the tilde character we can also use "/home/" and "\$HOME".

### Arithmetic expansion

You can use the command line as a calculator if you really want...

### Brace expansion

Brace expansion is pretty powerful when used correctly.

Patterns to be brace expanded may contain a leading portion called a preamble and a trailing portion called a postscript. The expression can contain either a comma separated list of strings or a range of integers/single characters. There can be no white space in the braces.

Below is an example of a great use for this sort of expansion:

```
[me@linuxbox me]$ mkdir Photos
[me@linuxbox me]$ cd Photos
[me@linuxbox Photos]$ mkdir {2017..2019}-{01..12}
```

```
[me@linuxbox Photos]$ ls
2017-01 2017-07 2018-01 2018-07 2019-01 2019-07
2017-02 2017-08 2018-02 2018-08 2019-02 2019-08
2017-03 2017-09 2018-03 2018-09 2019-03 2019-09
2017-04 2017-10 2018-04 2018-10 2019-04 2019-10
2017-05 2017-11 2018-05 2018-11 2019-05 2019-11
2017-06 2017-12 2018-06 2018-12 2019-06 2019-12
```

This example shows a fast way to create a list of directories to store photographs or any other sort of file that needs to be date organized.

### Parameter Expansion

This will be covered more later.

For now just consider how variables in bash may be utilised.

This command will print all shell variables.

```
printenv | less
```

## 4.3.2 Shell Arithmetic

As previously mentioned the shell allows arithmetic (use it as a calculator), this has wider implications when considering it's application to variables.

Arithmetic in the shell is the same for the most part as C, the list below is in order of their [presedence](#). (AKA, what order they will execute in, sort of like shell's version of BODMAS)

## 4.3.3 Variables

Variables can are in uppercase characters by convention.

In bash there are two kinds of variables:

### Global Variables

Variables that are available in all shells. These variables can be listed by using the 'env' or 'printenv' commands.

**Local Variables** Local variables aare only available in the current shell. Use the 'set' command without any options to list these variables and functions.

### Variables by content

Variables can be further divided into four other groups according to their contents:

1. String
2. Integers
3. Constants
4. Arrays

**Creating Variables** Variables are case sensitive and by default declared in capital letters. Declaring a local variable in lower case letters is also acceptable but not necessary. Basically follow your normal naming conventions with local variables and think of global variables like constants in C.

### Syntax for declaring a variable

```
#Global variable  
VARNAME="value"  
#Local variable  
varName="value"
```

### Syntax for exporting variables

```
export VARNAME="value"
```

Note that a child subshell can change variables locally not globally, any global changes need to be made where the variable was declared.

### Reserved Variables

Just like C there are some keywords/variables that are designated by the language. Therefore these variables cannot be changed.

| Variable name | Definition   |
|---------------|--|
| CDPATH        | A colon-separated list of directories used as a search path for the <b>cd</b> built-in command.  |
| HOME          | The current user's home directory; the default for the <b>cd</b> built-in. The value of this variable is also used by tilde expansion.                         |
| IFS           | A list of characters that separate fields; used when the shell splits words as part of expansion.  |
| MAIL          | If this parameter is set to a file name and the <code>MAILPATH</code> variable is not set, Bash informs the user of the arrival of mail in the specified file. |
| MAILPATH      | A colon-separated list of file names which the shell periodically checks for new mail.   |
| OPTARG        | The value of the last option argument processed by the <b>getopts</b> built-in.  |
| OPTIND        | The index of the last option argument processed by the <b>getopts</b> built-in.  |
| PATH          | A colon-separated list of directories in which the shell looks for commands.   |
| PS1           | The primary prompt string. The default value is <code>"\$-\\v\$ "</code> .   |
| PS2           | The secondary prompt string. The default value is <code>"&gt; "</code> .   |

## 4.4 Shell initialization files

### 4.4.1 System-wide config file

#### `/etc/profile`

All settings that should apply to all user environment's should be set here.

`/etc/bashrc` Useful file for creating aliases and adding applications to your path, it can also be used to autostart applications on Arch Linux.

Here is an example from my `.bashrc` file:

```
eval $(starship init ion)
#ignore upper and lowercase when TAB completion
bind "set-completion-ignore-case"
### ALIASES ###
alias nv='nvim'
alias ls='ls --color=auto'
```
